

Relief from Usury: Impact of a Community-Based Microcredit Program in Rural India

Vivian Hoffmann, IFPRI

Upamanyu Datta, World Bank

Abstract: The impact of micro-credit interventions on existing credit markets is theoretically ambiguous. Previous empirical work suggests the entry of a joint-liability lender may lead to a positive impact on the informal lending rate. We present the first RCT-based evidence on this question. Households in rural Bihar, India, were offered low-cost credit through a government-led self-help group (SHG) program, the rollout of which was randomized at the panchayat level. The intervention led to a dramatic decline in the use of informal credit as households substituted to lower-cost SHG loans, and to a reduction in average informal lending rates. Annual interest rates faced by landless households fell by 3 percentage points in treatment areas, reducing by half the gap in rates paid by landless versus landowning households. Two years after initiation of the program, significant positive impacts on asset ownership among landless households were apparent. Impacts on various indicators of women's empowerment were mixed, and showed no clear direction when aggregated, nor was there any impact on consumption value. Given the reduction in debt service costs achieved both directly through substitution into lower-cost sources of credit and the reduction in informal interest rates, impacts on household welfare may continue to accrue over time.

We are grateful for support from 3ie, the World Bank's Research Support budget, and by the contributions of (1) UK Aid from the UK government, (2) the Australian Departments of Foreign Affairs and Trade, and (3) the European Commission (EC) through the South Asia Food and Nutrition Security Initiative (SAFANSI), which is administered by the World Bank. We thank Arvind Kumar Chaudhuri, Ajit Ranjan, Shobha Shetty and Vinay Vutukuru for their advice and support. The views expressed here do not necessarily reflect the UK, EC or Australian government's official policies or the policies of the World Bank and its Board of Executive Directors.

1. Introduction

The vast majority of credit utilized by the global poor is from informal sources such as moneylenders, friends, or merchants (Banerjee and Duflo, 2007). Interest rates on these informal loans are typically high, particularly for the poorest, who borrow lower amounts and have little collateral to offer. A host of institutions, ranging from large commercial enterprises to small non-governmental organizations, have entered rural credit markets in recent years with the aim of providing lower-cost credit to the poor. While the impact of this so-called microfinance revolution on household level outcomes has how been well documented through a number of experimental and non-experimental studies, its effect on informal credit markets, which continue to supply the lion's share of credit in these settings, has received far less attention. We address this gap through an RCT based on the randomized roll-out of a government-led self-help group (SHG) program in the state of Bihar, India, which offered loans to SHG members.

According to government sources, 33.2% of all loans in rural India are from traditional moneylenders (GoI, 2014). Reliance on informal credit is even more pronounced in the state of Bihar, where 47.7% of outstanding debt held by farm households is from informal sources (RBI, 2007). Traditional moneylenders charge between 12 and 150 percent annual interest, compared to typical rates of 6 to 20 percent offered by formal banks on larger loans (RBI, 2011). In this context, the public, for-profit, and non-governmental sectors have all invested heavily in rural credit markets since the early 2000s (RBI, 2007; Galab and Rao, 2003, Brishti and Chowdhury, 2013).

The impact of these efforts depends, to a large extent, on how the entry of new sources of credit affects the availability of, and interest rates charged on, existing sources. As noted by Besley (1994), rural credit markets are likely to be characterized by multiple constraints and potential market failures, making the impact of external intervention unclear.

Entry of a new lender may push down the rates offered by existing lenders through three potential mechanisms. First, as long as either the demand for credit or its supply is responsive to price, an outward shift in the supply curve will lead to a drop in the equilibrium interest rate and to the exit of any incumbent lenders who find themselves unable to cover costs at the new rate. Second, if

informal lenders are earning supernormal profits, entry of competitors will push down rates but not impact on credit supply unless returns to capital in lending fall below those available in other (uncompetitive) sectors. Third, the availability of other sources of credit could enable borrowers facing repayment challenges with a way to service their debt and lower default risk, bringing down the administrative cost of lending identified by Banerjee and Duflo (2010) as a likely cost driver in the informal credit market. In contrast with the first two, this mechanism would be expected to have a weakly positive impact on credit supply.

The impact on lending rates need not be negative, however. If the new entrant is particularly good at identifying borrowers with a low likelihood of default, one of the commonly assumed advantages of the joint liability lending model used by SHGs and many other microfinance institutions (MFIs) (Ghatak, 1999), its entry could segment the market, driving up the average default risk of borrowers it does not serve and thus rates in the rest of the market (Demont, 2016; Mookherjee and Motta, 2016).¹ Access to a new outside lending option could also lead to moral hazard among borrowers, increasing default risk and thus lending rates. Finally, some authors have speculated that demand for credit from other sources could be increased by the entry of microfinance institutions, either because of the rigid repayment schedules imposed by MFIs, or the small size of the loans they offer relative to the cost of indivisible investments (Mallick, 2012; Kaboski and Townsend, 2012).

Empirical evidence on the impact of new lender entry on informal credit markets is thin. Three previous studies have used the approach of instrumenting for MFI entry, either using administrative targeting variables (Kaboski and Townsend, 2012) or the error structure of a predictive model of entry (Mallick, 2012; Berg, Emran and Shilpi, 2015). Two of these studies, both based on data from Bangladesh, find a positive impact of MFI entry on informal lending rates (Mallick; Berg, Emran and Shilpi), though in one case the effect is only significant when MFI coverage rates are high (Berg, Emran and Shilpi). Kaboski and Townsend, using data from Thailand, find no statistically significant impact on lending rates, but a small positive effect on the probability of default on other loans. Demont (2016), using panel data from the Indian state of

¹ While some prospective borrowers are actively screened out by MFIs and SHGs, capacity constraints may also limit the number who can be covered through such programs. This implies that while average default risk among the pool of borrowers from the informal market increases, there remain many low-risk borrowers within this pool.

Jharkhand, finds an inverse U-shaped relationship between SHG coverage and the rates charged by moneylenders, consistent with a model in which the SHG lender has superior information on borrowers' creditworthiness and serves those with lower risk of default.

The identification of causal impacts in these studies relies on the assumption that community characteristics associated with the entry of new lenders do not affect informal credit rates directly, and are not correlated with any unobserved factors that do. Given the multiple objectives of MFIs, which may include profit or at least cost-recovery as well as a social mission to assist the poor, it is impossible to sign the direction of potential bias in estimates from observational studies. The use of random assignment to a credit market intervention permits causal inference based on a much weaker set of assumptions. However, previous randomized evaluations of microcredit programs have not reported impacts on interest rates, presumably due to a lack of power on this outcome. The present study, which is based on the randomized roll-out of a government-led SHG program that offered microcredit and credit linkages to formal banks to the poor across 179 panchayats² in rural Bihar, overcomes this limitation.

Critical to the identification strategy, the SHG intervention had a strong direct effect on household use of informal credit. Just over two years after program initiation, households in panchayats selected for early roll-out were 51 percentage points more likely to include a member who belonged to an SHG than those in control areas. While borrowing from all sources increased overall during the study period, new borrowing from informal lenders was 18% lower in program panchayats compared to control areas, where households instead took advantage of the lower-interest loans offered by SHGs. We find that this exogenous shock to informal credit markets brought on by randomized SHG entry led to a fall of 3.8 percentage points in the average annual informal borrowing rate on a base of 68.8 percent.

Program impacts are generally more pronounced for landless households than for those that own land. Members of landless households were more likely to join an SHG and to take on more debt through the program, and the decline in lending rates is driven by a reduction in the lending rates faced by these households.

² Village government units typically consisting of between two and four villages.

In addition to its unique contribution to understanding how the entry of a new lending institution can affect informal credit markets, this study also contributes to the substantial recent literature estimating household-level impacts of access to group-based lending (Joshi and Desai 2014, Angelucci et al, 2015; Attanasio et al., 2015; Ausberg et al., 2015; Banerjee et al., 2015; Crepon et al., 2015). In general, this literature shows that even when an expansion in access to credit results in households taking on more overall debt, impacts can be quite limited in the short to medium run (Banerjee, Karlan and Zinman, 2015). While it is common to see shifts in livelihood activities, typically away from wage labor and toward self-employment, total household income is not generally affected. Similarly, impacts on overall consumption are rare, while reallocation away from “discretionary” spending (temptation goods, entertainment, and celebrations) is more commonly observed. Finally, there is limited RCT evidence that these programs affect indicators of female empowerment (Joshi and Desai, 2014)³.

Given previous findings, it is not surprising that, in the short-run, Jeevika, which did not have a significant impact on total borrowing, also did not lead to significant impacts on household asset ownership, livelihood activities, consumption level, or on women’s economic or decision-making roles or capabilities. In the high-indebtedness environment of rural Bihar, the primary impacts of the program were to shift a portion of households’ debt burden from high-cost loans on which monthly rates averaged over five percent per month, to much lower-cost SHG loans and to reduce the cost of borrowing from the informal sector. The estimated impact of Jeevika on households’ debt servicing costs is economically significant, but a longer time horizon may be required before this translates into measurable changes in the consumption or asset positions of households, or in the empowerment of women (Sanyal et al, 2015).

³ Non-experimental evidence using regression discontinuity designs or propensity score matching have also not shown any impact on income or consumption, but have shown substantial effects on women’s empowerment (Khanna, Kocchar and Palaniswamy (2015), Datta (2015), Desai and Joshi (2014).

2. Setting and intervention

At the time the program was initiated, Bihar was home to 32 million people living below the poverty line, and 66% of the rural population was landless (GoI, 2011). Rural Bihar had extremely low rates of participation in microcredit through Microfinance Institutions (MFIs) or Self Help Groups (SHGs) (World Bank, 2007). This prompted the Government of Bihar, with funding from the World Bank, to implement the Bihar Rural Livelihoods Project, also known as Jeevika, the Hindi word for livelihood. The primary aim of Jeevika was to provide disadvantaged groups, in particular the landless and members of the Scheduled Castes, access to (relatively) low-cost credit. When Jeevika enters a new village, Community Mobilizers employed through the program target households living in particularly poor areas, and encourage the women in these households to form self-help groups (SHGs) of 8 to 15 members. These groups then meet weekly, initially with a Community Mobilizer, who leads members through a curriculum on women's empowerment and provides basic literacy and numeracy training.⁴ Members are required to contribute a minimum of 2 Rupees (\$0.035 USD)⁵ each week toward a personal savings account held by the SHG. After several weeks of demonstrating consistent savings, an SHG is eligible to join the local Village Organization (VO), through which its members may access up to Rs. 50,000 (875 USD) in lending capital. SHGs can borrow these funds from the VO at a non-compounding interest rate of 1% per month, and SHG members may borrow at 2% per month. The mean credit available per SHG member is approximately Rs. 4300, assuming the average group size is halfway between the allowable minimum and maximum number of members. VOs are further federated into Cluster Level Federations (above the panchayat level), which then establish linkages to the formal banking sector. Over the longer term, Jeevika is also meant to deliver other development interventions and livelihoods training to SHG members, however these activities were not implemented in the study area during the period spanned by data collection.

⁴ SHG members are taught to sign their names, and how to read basic sign posts, such as bus names, etc.

⁵ USD equivalents are calculated using the average exchange rate from initiation of the program to the end of data collection.

3. Methods

3.1 Experimental design

In order to evaluate the impacts of Jeevika, the rollout of the project was randomized across 180 panchayats, randomly selected from within 16 blocks in seven districts where Jeevika was planning to scale up. In each of the study panchayats, one to two villages were then randomly selected for data collection.

Within each of the study villages, hamlets in which the majority of the population belonged to a scheduled caste or scheduled tribe were identified. Households were then randomly selected from these hamlets to be interviewed. A baseline survey was administered during July to October of 2011 to 8988 households across 333 villages in 179 panchayats.⁶ Following the baseline survey, panchayats were randomly assigned to an early rollout group or a late rollout group, after stratifying the sample on administrative block and the panchayat-level mean of outstanding high cost (monthly interest rate of 4% or higher) debt held by households at baseline. The project began in the early rollout panchayats between January and April 2012, and the follow-up survey was completed between July and September, 2014. Implementation in late rollout areas followed this round of data collection. Baseline and follow up surveys included detailed questions on debt, asset holdings, consumption expenditures, livelihood activities, and women's mobility, role in household decisions, and aspirations. In addition, in each village, a focus group discussion was conducted, through which data were collected on village level attributes such as local sources of credit, interest rates from each source, local wage rates, and the presence of or distance to markets and other institutions and amenities.

3.2 Analysis

The SHG intervention is expected to lead to a series of potential impacts, which we classify as direct, indirect and downstream. One or more direct impacts (increased SHG membership; increased utilization of credit through SHGs) is a necessary but insufficient condition for the

⁶ One of the selected Panchayats could not be surveyed due to political instability.

intervention to lead to indirect effects on informal credit markets. Changes in downstream outcomes (wealth, consumption level, women's empowerment) may follow from either direct or indirect impacts.

Based on the registered pre-analysis plan,⁷ we estimate the following ANCOVA specification to test the reduced-form, intent-to-treat impact of Jeevika on each group of outcomes:

$$y_{ivp2014} = \alpha_0 + \alpha_1 JEEVIKA_p + \alpha_2 y_{ivp2011} + (\alpha_3 X_{ivp}) + \alpha_4 S_p + \varepsilon_{ivp} \quad (1)$$

where y_{ivpt} is the outcome of interest for household i in village v in panchayat p in year t , $JEEVIKA_p$ is random assignment of the panchayat to early (2012) rollout of the intervention, X_{ivp} is a vector of pre-specified baseline controls used in the primary specification, S_p represents the vector of stratification dummies, and ε_{ivp} is a random individual-level error (notation constant across specifications for simplicity). In addition, to test for heterogeneous treatment effects on households that were landless at baseline, we estimate specification (2).⁸

$$y_{ivp2014} = \beta_0 + \beta_1 JEEVIKA_p + \beta_2 LL_{ivp} + \beta_3 LL_{ivp} * JEEVIKA_p + \beta_4 y_{ivp2011} + (\beta_5 X_{ivp}) + \beta_6 S_p + \varepsilon_{ivp} \quad (2)$$

where β_1 represents the treatment effect on land holding households, β_2 is the difference in outcome y between landed and landless households in control areas at follow-up, $\beta_1 + \beta_3$ is the treatment effect on landless households, and $\beta_2 + \beta_3$ is the difference in the outcome between the landed and landless at follow-up in the presence of the intervention.

Specifications (3) and (4) below mirror those above aside from the omission of non-stratification baseline controls, and are used to test for balance on key outcomes and demographic variables at

⁷ <https://www.socialsciceregistry.org/trials/570>

⁸ Analysis of heterogeneous effects based on both baseline landholdings and caste was specified in the pre-analysis plan for this study. There is significant overlap between the landless and SC/ST populations in the sample, and impacts on SC/ST households are very similar to impacts on the landless.

baseline.

$$y_{ivp2011} = \gamma_0 + \gamma_1 JEEVIKA_p + \gamma_2 S_p + \varepsilon_{ivp} \quad (3)$$

$$y_{ivp2011} = \theta_0 + \theta_1 JEEVIKA_p + \theta_2 LL_{ivp} + \theta_3 LL_{ivp} * JEEVIKA_p + \theta_4 y_{ivp2011} + \theta_5 S_p + \varepsilon_{ivpb} \quad (4)$$

Huber-White clustering of standard errors at the panchayat level is employed in all specifications. Since we test multiple hypotheses, many of which are closely related, we follow the earlier literature and include regressions of indices for each family of outcomes (as in Kling, Liebman, and Katz, 2007).⁹ P-values for these regressions are calculated using the step-down procedure in Hochberg (1988), which controls the family-wise error rate across all indices.

4. Results

4.1 Baseline credit access by landholding status

We begin the analysis with a description of credit use and costs, assets, and welfare indicators by landholding status at baseline. As shown in Table 1, landless households are more likely to hold any debt than those with land. They also have a larger number of loans than landowning households, but a lower mean level of outstanding debt, implying a smaller average loan size. This pattern echoes Banerjee and Duflo's (2010) discussion of the high administrative cost of lending to the poor. Indeed, the debt held by landless households is more expensive. Despite a lower overall level of indebtedness, landless households hold slightly more debt on which the monthly interest rate is 4% or higher, defined by Jeevika as "high-cost debt". The mean (simple) monthly interest rate paid by the landless is half a percentage point higher than that paid by landholding households, indicating an annual difference of 6 percentage points.¹⁰ Given the mean level of indebtedness,

⁹ See, for example, Banerjee et al. (2015)

¹⁰ Interest rates are generally non-compounding in this setting.

this difference implies an additional debt servicing cost of 569 Rs per annum, equivalent to 61.5% of the mean monthly consumption expenditure among the landless.

We also see that landless households have fewer interest-free loans. This suggests that informal risk-sharing mechanisms (which typically operate through gift giving or interest-free loans) are less available to landless households than to other households. Finally, the last four rows of Table 1 show that landless households are also economically disadvantaged in terms of their ownership of productive assets aside from land, and have lower material well-being in terms of ownership of durable consumption goods, housing quality, and consumption expenditures.

4.2 Balance at baseline

In order to establish the validity of the randomized assignment to early rollout, we test for pre-treatment balance across treatment and control groups in the primary outcomes of interest, as specified in the pre-analysis plan, and other important household characteristics. Differences in means for each variable are estimated through linear regressions in which controls for stratification variables are included and standard errors are clustered at the panchayat level. Results, shown in table A1 (column 1), indicate that households in treatment areas are 2 percentage points more likely to include an SHG member. This difference, while small, is significantly different from zero at the 5% level. Relatedly, the mean outstanding SHG debt is also higher in treatment areas at the 5% level, though the difference is small in economic terms (50 rupees). Monthly interest rates are higher in treatment areas, and this appears to be driven by a difference in informal lending rates alone. An index of productive assets, constructed according to the method proposed in Filmer and Pritchett (2001), is 0.1 points lower (0.06 of a standard deviation) in treatment areas as well. We also test for differences among landless and landed households in treatment versus control areas (columns 2 and 3). Again we find small differences in SHG enrollment and debt, and in asset holdings. Attrition, at 3%, is low given the three-year interval between surveys, and does not differ between treatment and control areas, indicating that differential attrition is not likely to drive the results.

4.3 Direct impacts: SHG membership and borrowing

Table 2 presents estimates of the impact of access to Jeevika on SHG membership and outstanding

debt to SHGs; overall loans taken, amount borrowed and interest rates. Results shown in columns 1 and 2 of Panel A indicate that over 60% of households in treatment areas had at least one member in a self-help group by follow-up, compared to 10% of households in control areas. Given the higher interest rates and lower use of credit among the landless at baseline, landless households had the most to gain through participation in Jeevika. Consistent with this, we find that take-up of the program is more pronounced among these households, who were 11 percentage points more likely to belong to an SHG than landowning households in program areas (Panel B).

While the program appears to have had a slight negative impact (Rs. 860, $p < 0.1$) on the total amount of outstanding household debt (column 3), we see a significant increase of close to Rs. 2000 in the value of debt owed to SHGs (column 4), and an offsetting decrease in loans from informal sources of credit (Table 3, column 2).¹¹ Scaling the increase in SHG debt by program-induced SHG membership, 91% of the lending capital transferred to groups through Jeevika had been extended as credit to households at the time of the follow-up survey.

The magnitude of first-order program effects differs by landholding status. The increase in SHG debt is higher among the landless than the landed by Rs. 390. In contrast, the negative impact of the program on new informal debt is twice as large among land-owning households (Table 3, column 3, panel B), reflecting lower baseline borrowing among the landless. The large decrease in informal borrowing among landholding households exceeds the expansion in loans taken through SHGs by these households, resulting in a marginally significant negative estimate of the program effect on overall indebtedness for this subsample (Table 2, column 3), and a significant decrease in overall borrowing over the past year (column 7). For landless households, on the other hand, the expansion in SHG borrowing exceeds the decline in informal borrowing, with a positive (but not significant) point estimate on total new borrowing. Overall, the lack of an impact on overall borrowing suggests that on average, this population was not credit constrained prior to the intervention.

The substitution in loan source results in a strong negative effect on the average interest rate on

¹¹ Informal sources include moneylenders, shopkeepers, neighbors, friends, relatives, chit funds, casual employers, casual employees and village temples. We exclude interest free loans, which likely reflect informal risk-sharing mechanisms rather than the informal credit market.

households' outstanding debt, and on the amount of debt for which the monthly interest rate is 4% per month or higher. On average, such "high cost" debt is Rs. 1880 lower in treatment areas by the endline, a 14.5% reduction relative to control panchayats. Credit was offered through Jeevika SHGs at a monthly rate of 2%, less than half the mean baseline informal lending rate. Together with the high levels of loan take-up through the program, this implies a strong direct impact on the average interest rate paid by households on recent loans. Mean monthly rates paid on all loans taken within the past 12 months were a full percentage point lower in program areas, a reduction of 20% compared to control panchayats.¹² The impact on interest rates is especially pronounced for landless households, who faced higher rates at baseline. Jeevika reduces the difference in average borrowing rates among faced by landholding and landless households by two thirds (Table 2, panel B, column 6).

We also see (in column 2) that access to Jeevika resulted in 4 percentage points more households borrowing at all, indicating impacts on the extensive margin apart from the intensive margin discussed above. Overall, at the household level, this is consistent with findings in Mexico by Karlan, Mullainathan and Zinman (2009) - that price reductions led to more borrowers as well as larger loan sizes.

4.4 Indirect impacts: Informal credit rates and lenders

Despite the significant resources made available for household borrowing through Jeevika, and the high take-up of the program, even in program areas 65% of the increase in outstanding debt between the baseline and follow-up surveys was from informal lenders. This underscores the importance of understanding the impact of this and other microcredit interventions on the informal credit market.

As seen in Table 3 (column 4), our results indicate that Jeevika led to a reduction of 0.11 in the average monthly lending rate paid by households on loans taken from informal lenders over the past 12 months ($p < 0.1$). Splitting the sample by new versus repeat borrowers (those who had not taken an informal loan within 12 months of baseline versus those who had), we see that this reduction is driven entirely by repeat borrowers. This could be due to an assumption by lenders,

¹² The household average interest rate excludes any interest free loans.

along the lines of the Demont (2016) and Mookherjee and Motta (2016) models, that unknown lenders who are not able to satisfy their credit needs through SHGs are likely to be high-risk.

A weakness of using household-level data to estimate impacts on lending rates is that these are affected by the composition of borrowers, which is itself likely to have been affected by the intervention. If households known to lenders as low-risk borrowers (and therefore receiving preferential rates on loans) are also more likely to receive credit through an SHG, this would lead to an upward bias (toward zero in this case) of the intervention's effect on rates, since the compositional change in borrowers from informal sources would increase the average informal rate.

Data collected through village-level focus group discussions, on the other hand, aimed to get at the publicly known cost of informal credit in each village. While this rate is certainly not immune to the composition of borrowers, we expect that it should be less affected by the identity of borrowers than household-level data. The point estimate of the intervention's impact on interest rates using these village-level data is indeed larger than that obtained using household data.¹³ Overall, informal lenders (including professional moneylenders, shopkeepers, relatives and friends) are reported to charge 0.32 percentage points less per month in villages where Jeevika was present (Table 3, column 7, Panel A). Data from focus group discussions also indicate a decline in the overall number of informal sources mentioned in focus group discussions (Panel B, column 7). This is driven by fewer friends and relatives listed as sources of credit; there is no significant impact on the number of professional moneylenders or shopkeepers (Panel B, columns 8 and 9).

As shown in Figure 1, which illustrates the distribution of monthly interest rates from informal sector borrowing over the past 12 months by treatment group at pre and post intervention, the 2% lending rate offered by Jeevika is barely represented, providing confidence that the impact on informal sector rates is not driven by misclassification of SHG loans as informal loans.

As discussed in the introduction, a downward shift in lending rates could occur through one of three channels. It could be a pure demand effect, due to an inward shift of the demand curve that

¹³ Controls in this case are village-level means of the household-level baseline variables included in the models with household-level outcomes. For villages with no rate recorded at baseline, the mean rate at the panchayat (16 observations) or district (2 observations) level is used.

traditional lenders face, it could be the effect of the competitive pressure exerted by a new entrant into a non-competitive market, or it could be due to decreases in the administrative costs associated with lending.

Results shown in Table 3 provide some insights into potential mechanisms. First, we note that both the average amount borrowed from informal sources and the proportion of households who borrow from informal sources at all are negatively affected by the intervention (column 1). This is the case for both landless and land holding households, though land-holders exhibit a stronger effect on the intensive margin. Focusing on results in panel B, we also see that the decline in informal interest rates is driven by the decline in rates faced by landless households specifically (column 4). If the same credit market is used by landless and landed alike, a drop in demand for credit should affect the rates faced by both groups equally. On the other hand, if the credit markets used by the two groups are segmented, we would expect to see a sharper fall in rates for the landed, whose demand for informal loans dropped most steeply. The drop in interest rates faced by landless households specifically therefore appears to represent either an erosion of supernormal profits earned by the informal lenders who serve landless households, or arise through a reduction in the cost of lending to this segment of the market.

Looking at the impact of being landless in the treatment area, we see that Jeevika reduced the wedge in informal monthly interest rates between landless and landholding households by 50%, from 0.48 percentage points to 0.24 percentage points.

4.5 Downstream impacts: Assets, consumption and women's empowerment

While Jeevika had immediate and dramatic effects on credit markets in targeted villages, we see more limited short-term impacts on household asset possession, material well-being or various measures of women's economic and social empowerment (Tables 4 and 5). We do see significant positive effects of the program on asset holdings among landless households (Table 4). Consumption assets, productive assets, and housing quality are all significantly affected within this sub-group.

The program's effect on women's empowerment is less clear. We see a positive impact on an index of collective action, but a negative impact on women's role in decision-making within the

household (both $p < 0.1$). These two effects cancel each other out in the aggregated index for this family of outcomes, resulting in an estimated family-wise treatment effect of zero.

4.6 Robustness tests

In the presence of a baseline difference in outcomes, the ANCOVA estimator is generally less biased than either the simple difference or difference-in-difference estimators, which tend to under- or over- correct for the baseline difference respectively (Frison and Pocock, 1992). For direct and indirect household-level impacts shown to be statistically significant under ANCOVA, we present these two alternative estimators as upper and lower bounds of the true effect in Tables A2 and A3.¹⁴ Treatment effects are similar in magnitude and significance under these alternative specifications. In fact, the estimated impact on informal interest rates in the overall sample is larger in magnitude, and differs from zero at a higher degree of statistical significance in the case of the simple difference estimator (A3, panel B, column 4). This result provides reassurance for the validity of interest rate results, as baseline imbalance for this variable goes in the opposite direction as the estimated treatment effect.

5. Discussion

Chronic indebtedness and exploitative moneylenders are well-established tropes in the fictional and cinematic accounts of poverty in rural India. Several studies, including an important recent survey by the National Sample Survey (NSS, 2014) and technical papers by the Reserve Bank of India (RBI 2007, RBI 2011) have documented the widespread reliance of rural households on high-cost debt from the informal sector at rates of up to 150 percent per annum. Over the past two decades, micro-finance institutions have rapidly expanded into markets previously served almost exclusively by traditional moneylenders. One would expect this influx of competition to affect existing credit markets, but the nature of these impacts are not obvious *ex ante*.

The limited empirical literature on this question consists of observational studies and finds zero or positive impacts on lending rates charged by informal sector lenders. Despite the existence of a large literature on the impact of micro-credit programs, no randomized impact evaluation to date

¹⁴ Results for downstream outcomes generally remain insignificant under these alternative specifications and are not shown.

has documented a significant effect on interest rates. This is the first study to do so. The randomized roll-out evaluated in this study, conducted in seven of the 38 districts of Bihar, increased self-help group (SHG) membership by 50 percentage points. Those who joined a Jeevika SHG shifted almost 30% of their outstanding household debt from the informal sector to Jeevika, on average. The massive influx of relatively low-cost credit extended through Jeevika allows us to detect, for the first time, the impact of a micro-finance intervention on informal credit markets through a randomized evaluation.

At baseline, annual informal interest rates paid by landless households were an average of 6.1 percentage points per year higher than those paid by the landed. SHG entry caused a shift in the informal lending rate offered to these households that reduced this gap by 50%, whereas the point estimate of the impact on rates paid by landowning households is within a quarter of a percentage point of zero per annum. The fact that the impact on lending rates is limited to the economically marginalized is indicative of the segmented nature of credit markets in this context.

Using the impact on the overall informal interest rate based on the focus group data (-0.32% / month), and assuming that households' informal debt can eventually be refinanced at the lower prevailing rate, we estimate that Jeevika will reduce the average cost of servicing debt to informal creditors by Rs. 624, equivalent to 90% of the mean monthly reported consumption expenditure in this sample. The magnitude of this effect is comparable to the direct average annual savings of Rs. 886 achieved by shifting a portion of household debt out of the high-cost informal sector to lower-cost SHG loans.

Two years after initiation of the program, a significant impact on the asset position of landless households was already observed. No impact on consumption expenditures was seen, and only weak and conflicting effects on various measures of women's empowerment were seen. Given that the intervention reduced debt servicing costs substantially, it is possible that asset impacts will strengthen with time, and that other downstream impacts may still arise.

<i>Treatment if landed</i>						0.70

Notes: Standard errors clustered at the panchayat level shown in parentheses. Coefficients are from an ANCOVA specification - linear regressions of each outcome on its value at baseline, and an indicator of treatment status; panel B has linear regressions of each outcome on indicators of treatment status, landlessness, and their interaction. All specifications control for block dummies and mean high cost debt at the panchayat level at baseline. Additional controls († in Table 1) are included in even-numbered columns. Landless status is landlessness at the time of the baseline survey.

Column 6 presents coefficients in a regression of z-scores of the outcome variables in this "family" - working women, decision making, collective action, mobility, aspirations - following Kling, Liebman, and Katz (2007). p-values for these regressions are reported using Hochberg's step-down method to control the FWER across all index outcomes.

* p<0.1, ** p<0.05; *** p<0.01

Additional baseline controls?	no	no	no	no	no	no
Hochberg-corrected p-values						
<i>Treatment if landless</i>						0.00
<i>Treatment if landed</i>						0.21

Notes: Standard errors clustered at the panchayat level are shown in parentheses. Coefficients are from an ANCOVA specification - linear regressions of each outcome on its value at baseline, and an indicator of treatment status (plus an indicator of landlessness at baseline and its interaction with treatment status in Panel B). Stratification dummies are included in all specifications.

Columns 6 presents coefficients in a regression of z-scores of the outcome variables in this "family" - consumption assets, productive assets, housing quality, access to entitlements, real consumption per adult equivalent - following Kling, Liebman, and Katz (2007). p-values for these regressions are reported using Hochberg's step-down method to control the FWER across all index outcomes.

* p<0.1, ** p<0.05; *** p<0.01
